Taking control over car

ANDY GREENBERG SECURITY 08.01.16 03:30 PM

THE JEEP HACKERS ARE BACK TO PROVE CAR HACKING CAN GET MUCH WORSE

Security researchers Charlie Miller and Chris Valasek.  WHITNEY CURTIS FOR WIRED

- Wired January 8th, 2016
- Somehow gained access to internal CAN bus commands
- CAN bus access originally required physical access to connector within car

ALMOST EXACTLY A year ago, Chrysler announced a recall for 1.4 million vehicles after a pair of hackers demonstrated to WIRED that they could remotely hijack a Jeep's digital

DoS attack against building automation

Verkkohyökkäys katkaisi kahdesta kerrostalosta lämmöt Lappeenrannassa – ”Laajuus ja voima on aika poikkeuksellinen”

Useat rakennusten automaatiojärjestelmät ovat eri puolilla Suomea ”tiltanneet” palvelunestohyökkäysten vuoksi. Kuinka nettihakkeri voi katkaista kerrostalosta lämmöt?

Palvelunestohyökkäys katkaisi hetkeksi huoneistojen ja veden lämmityksen. (KUVA: MOSTPHOTOS)

Anu-Elina Ervasti HS

Julkaistu: 7.11.2016 19:10

KAHDESSA Lappeenrannassa sijaitsevassa kerrostalossa tapahtui viime viikon torstaina jotain poikkeuksellista: palvelunestohyökkäys katkaisi hetkeksi huoneistojen ja veden lämmityksen.

- Lack of prioritization of basic control functionality?

DDoS attack in 2016

Friday morning saw the [largest internet blackout in US history](#). Almost every corner of the web was affected in some way -- streaming services like Spotify, social sites like Twitter and Reddit, and news sites like Wired and Vox appeared offline to vast swathes of the eastern seaboard.

After suffering three separate distributed denial-of-service (DDoS) attacks, Dyn, the domain name system provider for hundreds of major websites, recovered and the web started to spring back to life.

The flooding attack was designed to overload systems and prevent people from accessing the sites they want on a scale never seen before this.

All signs point to a massive botnet utilizing the Internet of Things, powered by [malware known as Mirai](#), which allows the botnet's operator to turn a large number of internet-connected devices -- surveillance cameras, smart home devices, and even baby monitors -- against a single target.

In this case, it was Dyn's servers.

"We're seeing attacks coming from an Internet of Things botnet that we identified called Mirai, also involved in this attack," said Dale Drew, chief security officer at Level 3, in [a live stream on Friday](#), during a time where information about the attack was still scarce.

Dyn later said Saturday in a blog post that the attack was "highly distributed" and involved "tens of millions of IP addresses."

SPECIAL FEATURE

IoT: The Security Challenge

The Internet of Things is creating serious new security risks. We examine the possibilities and the dangers.

[Read More](#)

➤ ZDNet, October 22, 2016

➤ **WAIT!!**

- Why blame IoT for this? IoT has nothing to do with it!
- Gateways, Smart TVs etc would be there anyways, even without IoT

IoT vulnerabilities

- Devices and buses made for local use are connected directly to the internet
 - Can be attacked by anybody easily
 - Example: Modbus TCP used in Building Automation
 - Port can be found with port scanning
 - If Modbus registry map is known, even direct control may be possible
 - Or just confusing controller by sending random commands
- Firewall configuration is not easy to get right
 - Did you ever try opening only one port on your home gateway?
 - Remains risky even for professionals
- Cryptographical identities are still rare for IoT devices
- Etc etc

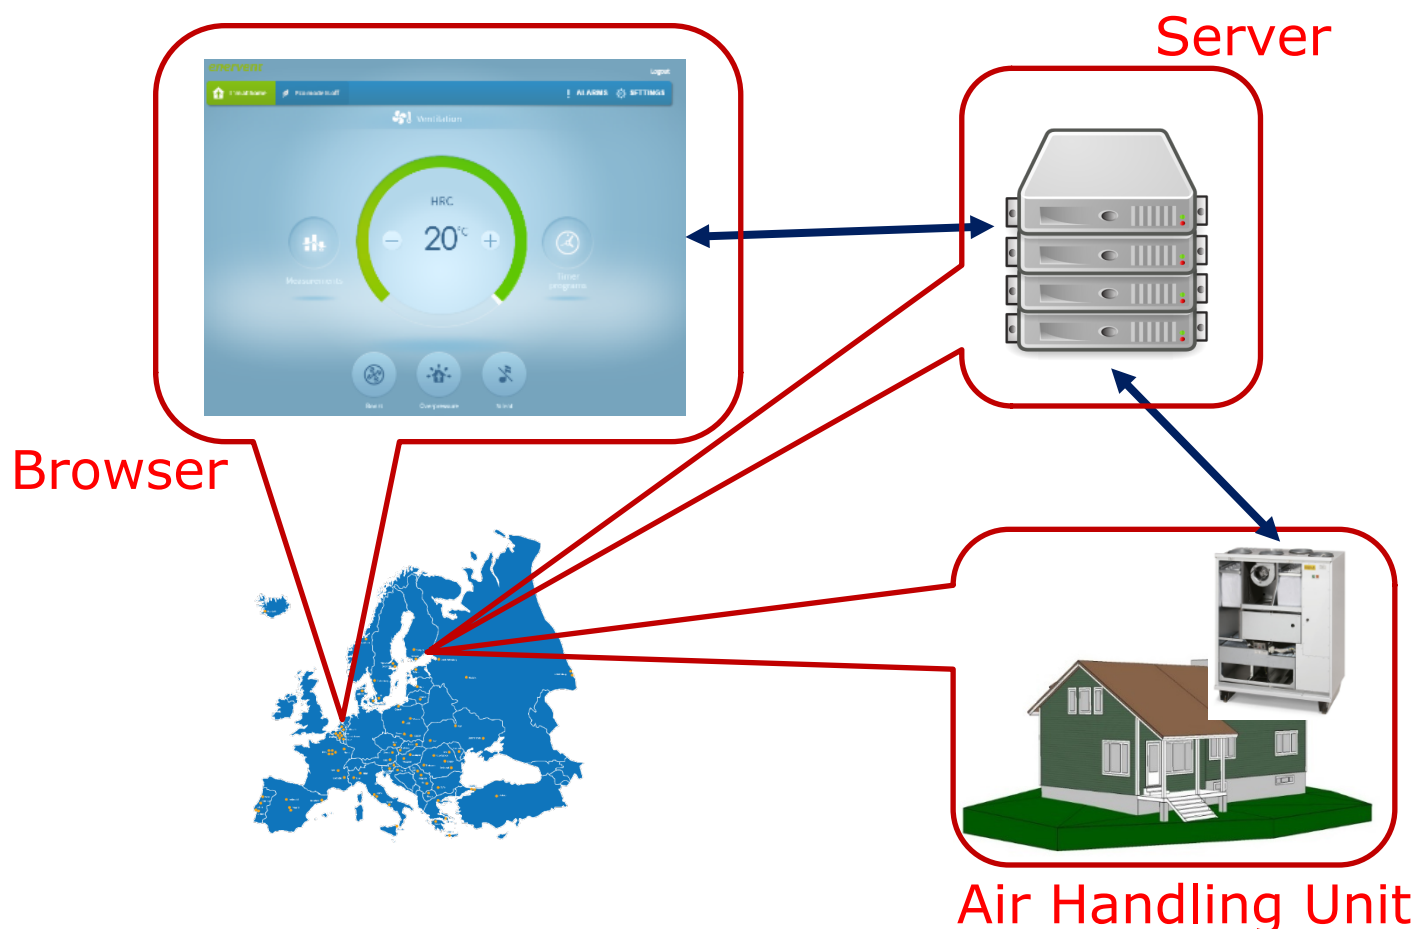

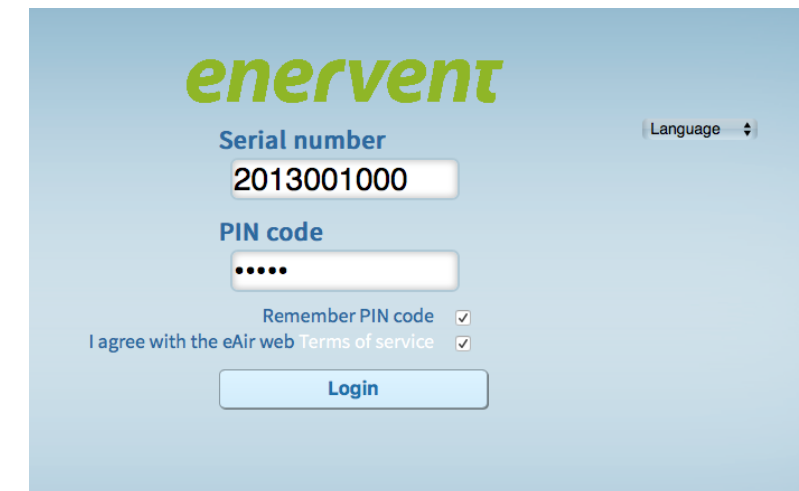

A secure IoT system?

- Unique identities
- Machine authentication by certificate
- User authentication by serial number + PIN

Every machine ships with:

- Serial number
- PIN code
- X.509 certificate

- All communication secured by HTTPS
- Bi-directional control by WebSockets
- Commercially available since 2013
- Why is this not the norm?

Security basics

Identity and Identification

- All **entities** need **identity**
 - People, devices, organizations, code, agents, ...
- Identity must be **unique** in context of use
 - IoT: usually **globally unique**
 - “Our” approach from 2001: **ID@URI**
- Most things have **more than one identifier**
 - Name, social sec. number, fingerprint, ...
 - Licence plate number, VIN number, ...
 - Different identifiers in different **roles** and different means of **authentication**

Authentication

- How **validate identity**?
- Needed for determining
 - **Level of trust**
 - **Level of access**
- Authentication depends on **identification support**
 - User name, password (local authentication)
 - Kerberos, Shibboleth, ... (network authentication)
 - OAuth, OpenID Connect (delegated trust)
 - Public-private key certificates (PKI)

*Also look e.g. at The Open Group Jericho Forum video:
<https://www.youtube.com/watch?v=ZlG3yZfk9tw&feature=plcp>*

Authorization / Access control / Entitlement

- **Who** gets access to **what** information?
- **Operations**
 - Read, write, execute, ...?
- Different entities may act in different **roles** or **personas** depending on the **context**
- **Access rights** depend on **authenticated role**

*Recommended reading and video (The Open Group Jericho Forum):
<https://blog.opengroup.org/2012/08/07/entities-and-entitlement-the-bigger-picture-of-identity-management/>*

Security specifics for IoT

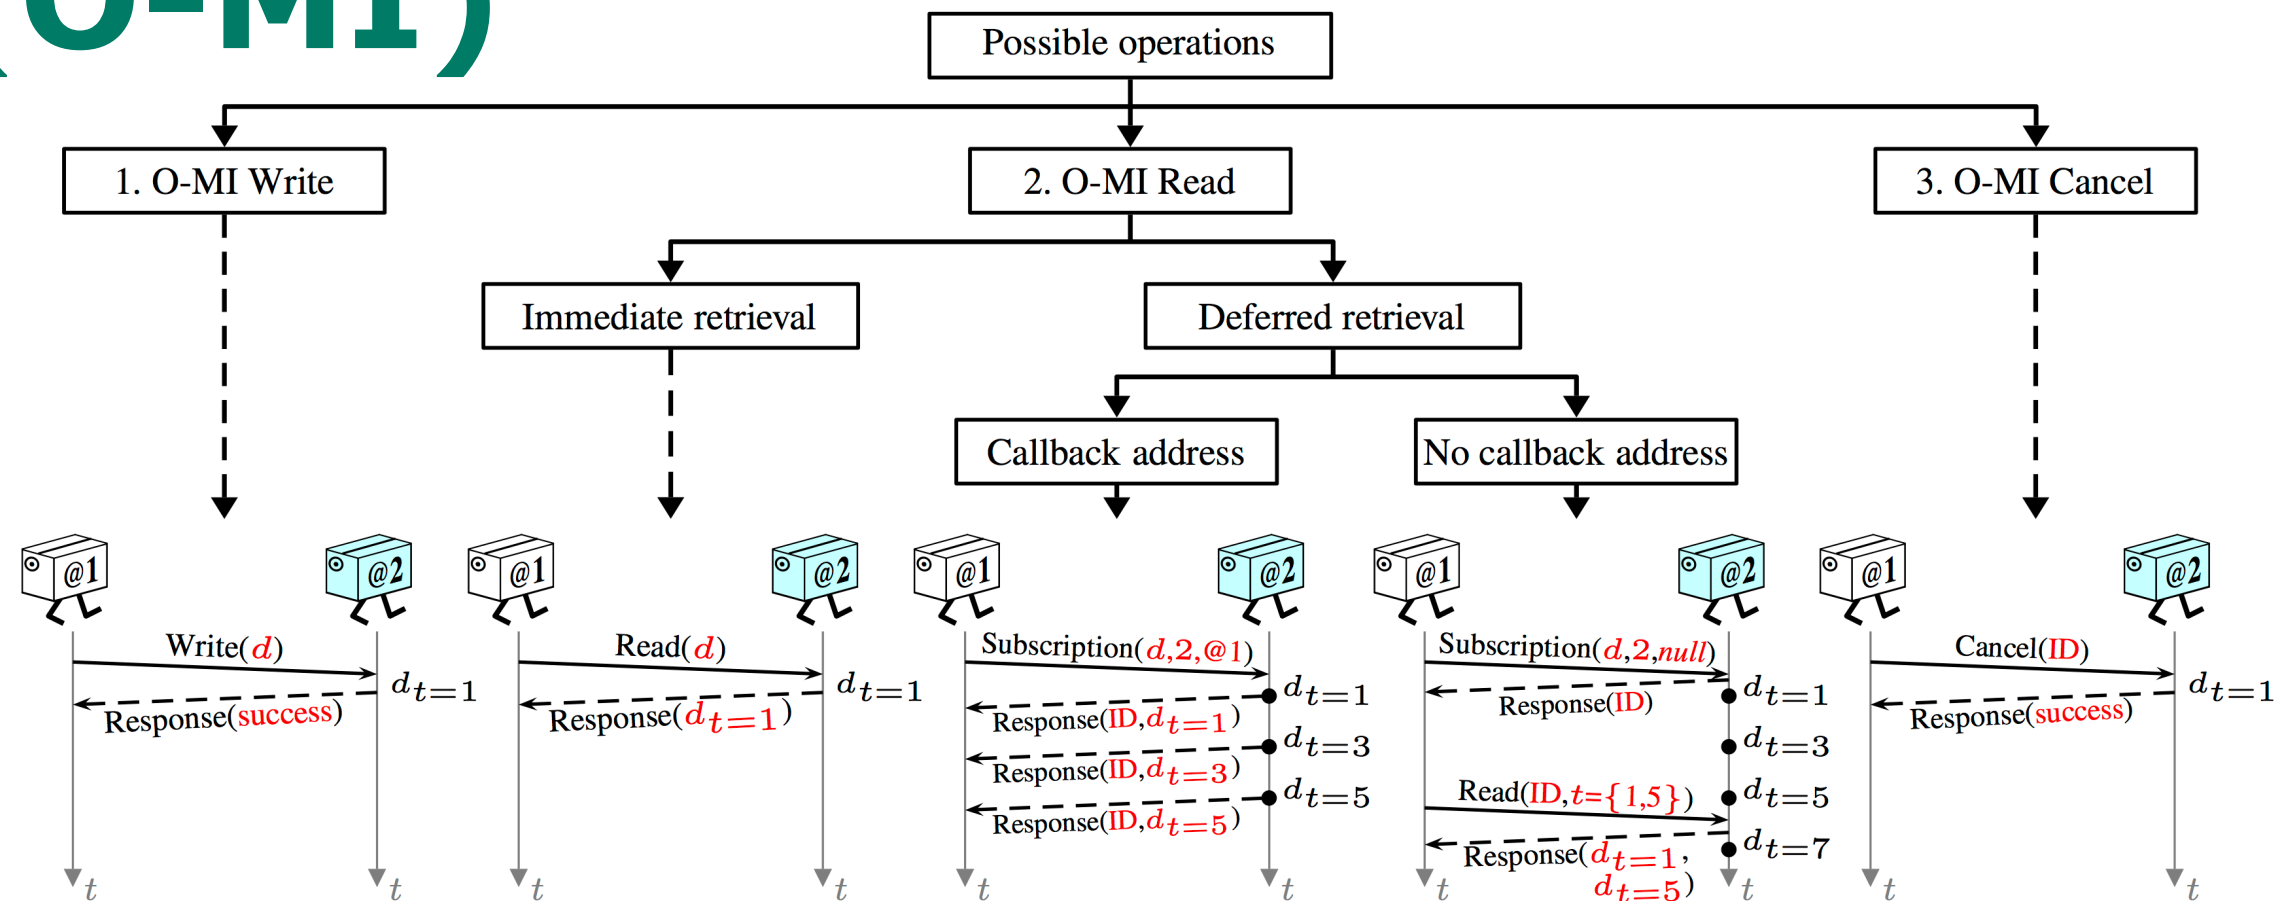

- Most security basics can be applied as such
- Challenges:
 - How identify pieces of information for access rights, as for folders and files in a file system?
 - Distribution of identities (/certificates) to devices, code, ...?
 - Device-level, owner-level, organization-level, ... certificates?
 - How to update certificates before they expire?
 - How to manage software updates to all those devices behind firewalls etc?

Security in O-MI / O-DF reference implementation

Identification and Authentication

- All Objects in O-DF have identities (compulsory <id> tag)
 - However, these are mainly for annotating information, not for security
- Users identified / authenticated by
 - User name, password
 - Shibboleth
 - Oauth
- Things / gateways /systems identified by
 - Public-private key certificates (PKI)
 - Client Authentication with HTTPS

Open Messaging Interface (O-MI)

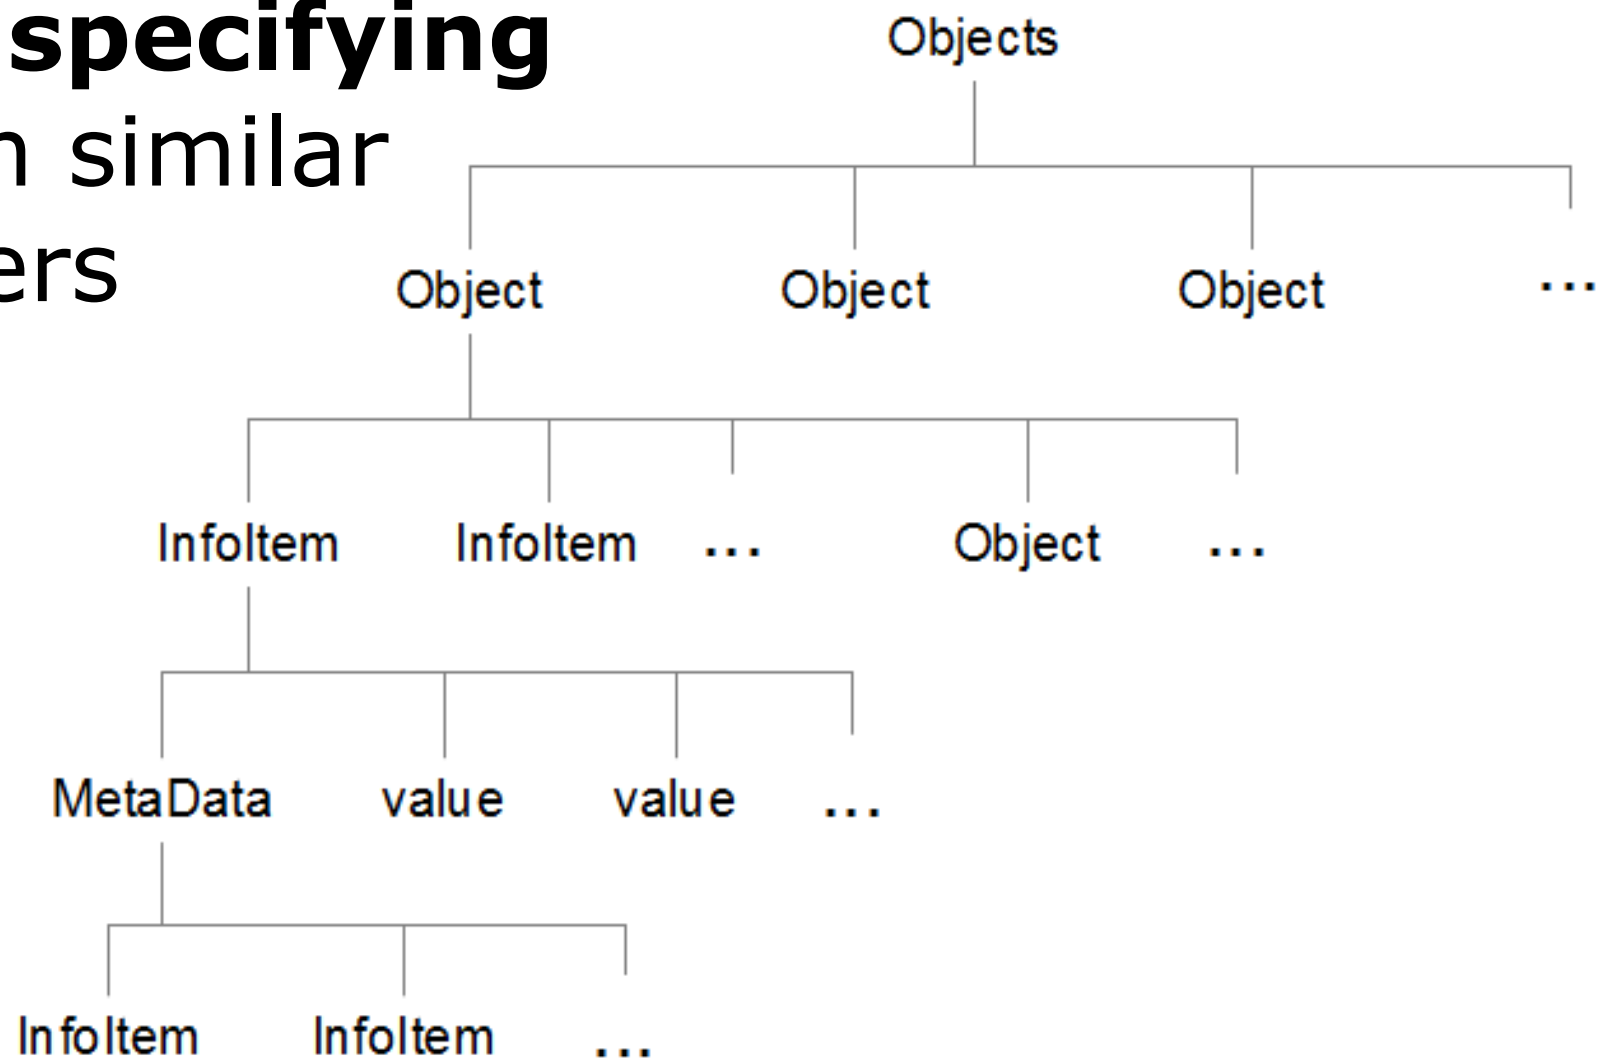

➤ Specifies **possible operations**

- **Read** current and historical information, alerts, other events, ...
- **Write** information, such as sensor values, setpoints, alerts, ...
- **Subscribe** to information with or without callback
- **Cancel** subscriptions before they expire
- Upcoming: **call** (execute) methods

Open Data Format (O-DF)

- **Generic object tree** for IoT (or other) data structures
- Can be used for **specifying access rights** in similar ways as for folders and files in a file system

Access Control Management UI

The screenshot displays the 'O-MI Access Control Module' interface. At the top, a header bar includes 'Version 0.1', 'Server /omi/node/', and 'URL'. A 'Documentation' link is visible in the top right. The main interface is divided into three sections: 'O-MI Access Groups', 'AC Tree', and 'Users'. The 'O-MI Access Groups' section has a 'Select group' dropdown. The 'AC Tree' section, titled 'Select nodes for wh', shows a hierarchical tree of objects including 'OMI-Service', 'K4', 'SmartHouse', 'FrontDoor' (selected), 'BackDoor', 'Kitchen', 'BedRoom', 'CS Building', 'K1', 'KarysHouse', and '2013001000@'. The 'Users' section has an 'Add user' button. A 'New Group' dialog box is open in the center, featuring a close button (X) in the top right. The dialog has a field for 'Name*' with the value 'New Group'. Below this is an 'Add Users' section with a list of users, including 'Roman Filippov [filiroman.tsu@gmail.com]'. At the bottom of the dialog are 'Cancel' and 'Save' buttons. In the background, a code editor shows the snippet `version="1.0" ttl="0">`.

Making it work

Sensing using 1-wire sensors

O-MI&O-DF Reference
Implementation Sandbox

Internet
O-MI&O-DF

O-MI
O-DF

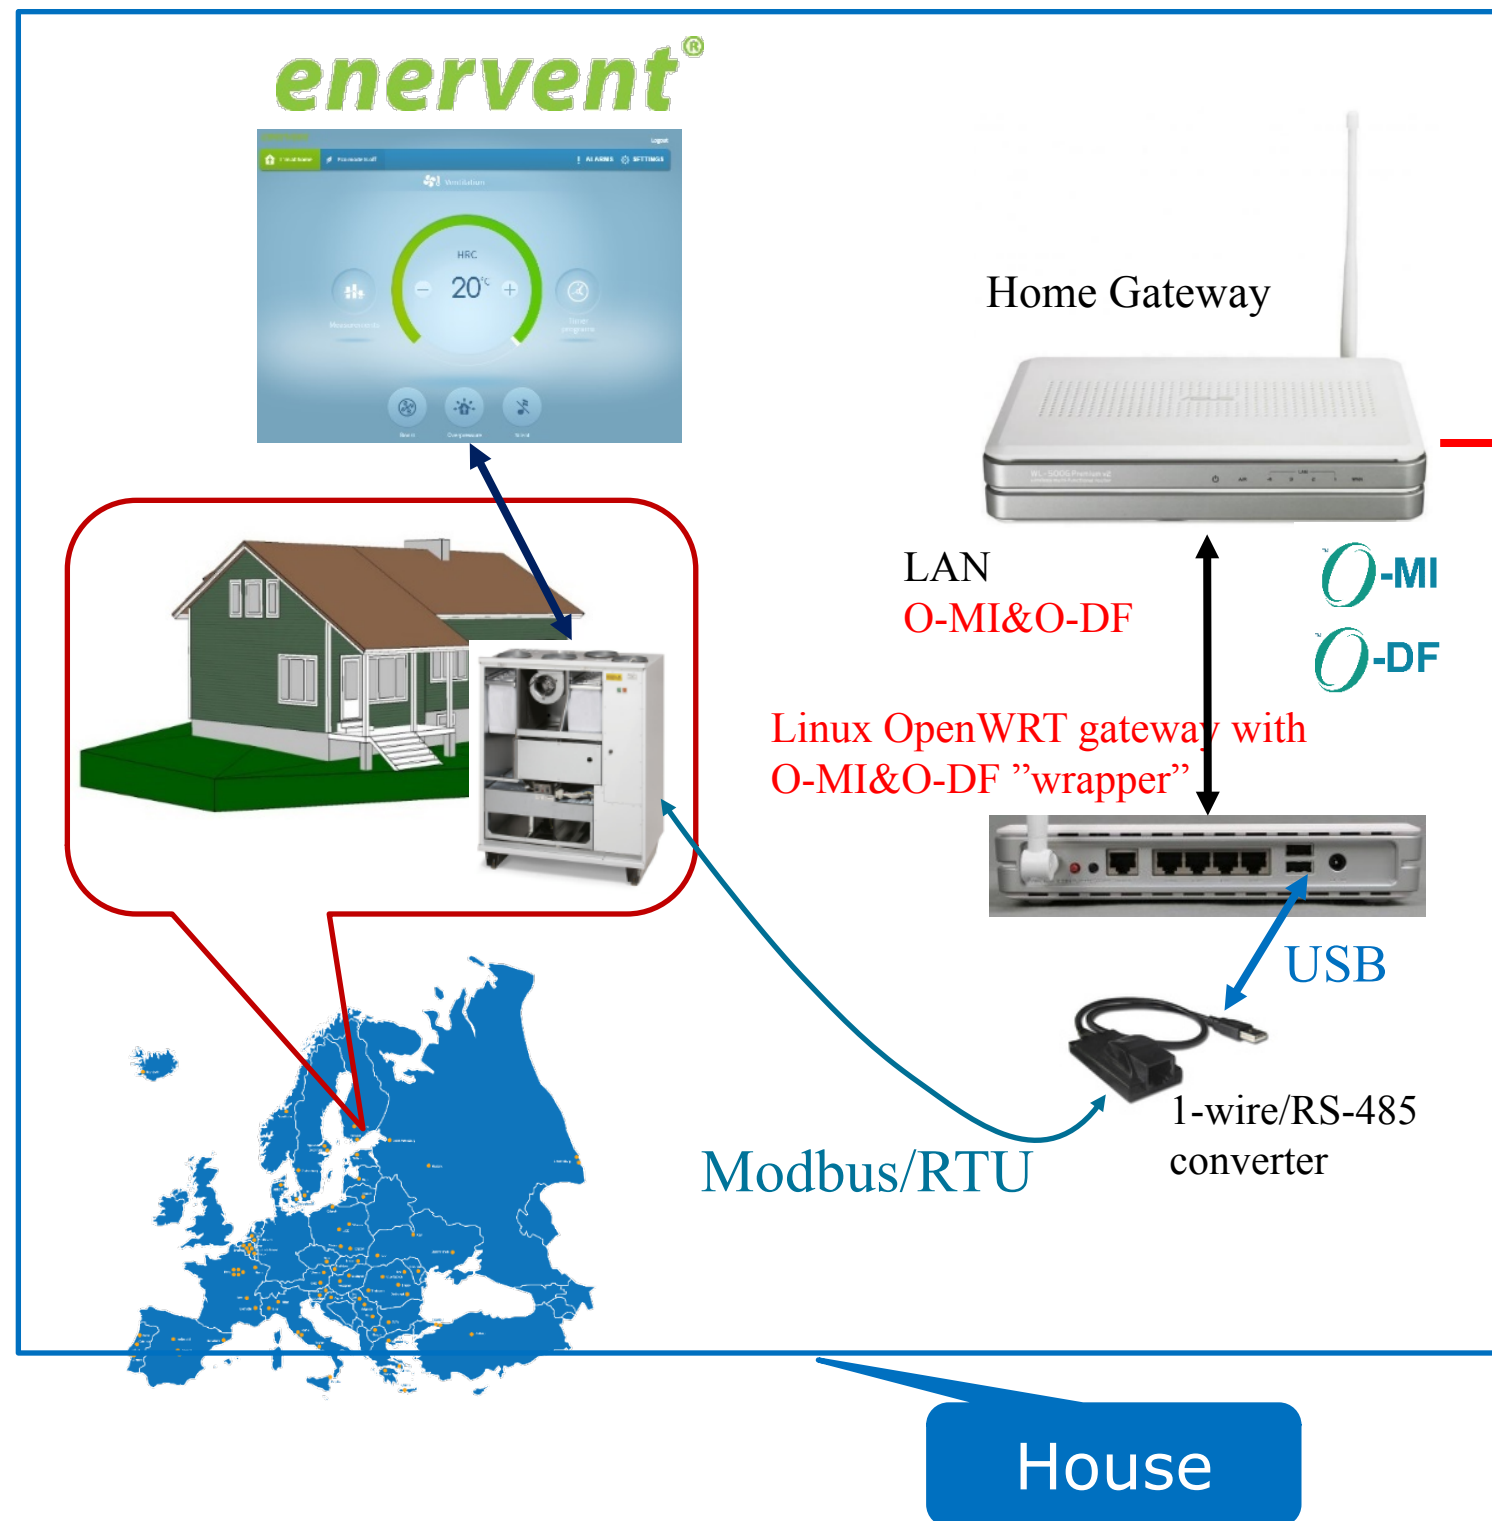

1-wire sensing "under the hood"

- Retrieve sensor values, create O-MI write with O-DF payload
 - Shell scripts running on OpenWRT Linux, about 20 lines of code
- Send with **curl**:

```
*/10 * * * * /usr/bin/curl --header "Content-Type:text/xml;charset=UTF-8" --cert-type "pem" --cert "/root/client.pem:xxx_xxx" --cacert "/root/chain_TERENA_SSL_CA_2.pem" --data "`/root/test_omi_write.sh`" "https://otaniemi3d.cs.hut.fi/omi/node/" > /dev/null
```

Internet O-MI&O-DF

User Interface

Air Handling Unit "under the hood"

- Retrieve sensor values, create O-MI write with O-DF payload
 - Shell script running on OpenWRT Linux, about 3 lines of code per value to retrieve
- Send with **curl**

```
*/10 * * * * /usr/bin/curl --header "Content-Type:text/xml;charset=UTF-8" --cert-type "pem" --cert "/root/client.pem:XXX" --cacert "/root/chain_TERENA_SSL_CA_2.pem" --data "`/root/test_omi_write.sh`" "https://otaniemi3d.cs.hut.fi/omi/node/" > /dev/null
```

Recall: Security specifics for IoT

- Most security basics and existing technologies applied as such
- Available operations specified by O-MI
- Access Control specified using O-DF Objects and InfoItems
- Remaining challenges:
 - Certificates are currently signed by the receiving O-MI node
 - Distribution of identities (/certificates)?
 - Device-level, owner-level, organization-level, ... certificates?
 - How to update certificates before they expire?
 - How to manage software updates to all those devices behind firewalls etc?
 - Current and Future operations in O-MI: Callback, Execute, Delete
 - Generic requests based on Object type etc: O-DEF (Open Data Element Framework) could help!

Trust-based Identity Overlay model

ControlThings

Excellence Embedded

Example: Car arriving in town

Find parking
place close to ...
I'm driving in street
xxx, location yyy

Street
temperature is...

Just drove into
hole in the street!

Need to charge
my EV battery, N
kWh...

ESP system
activated,
slippery!!

Parking/ EV
charging place
reserved...

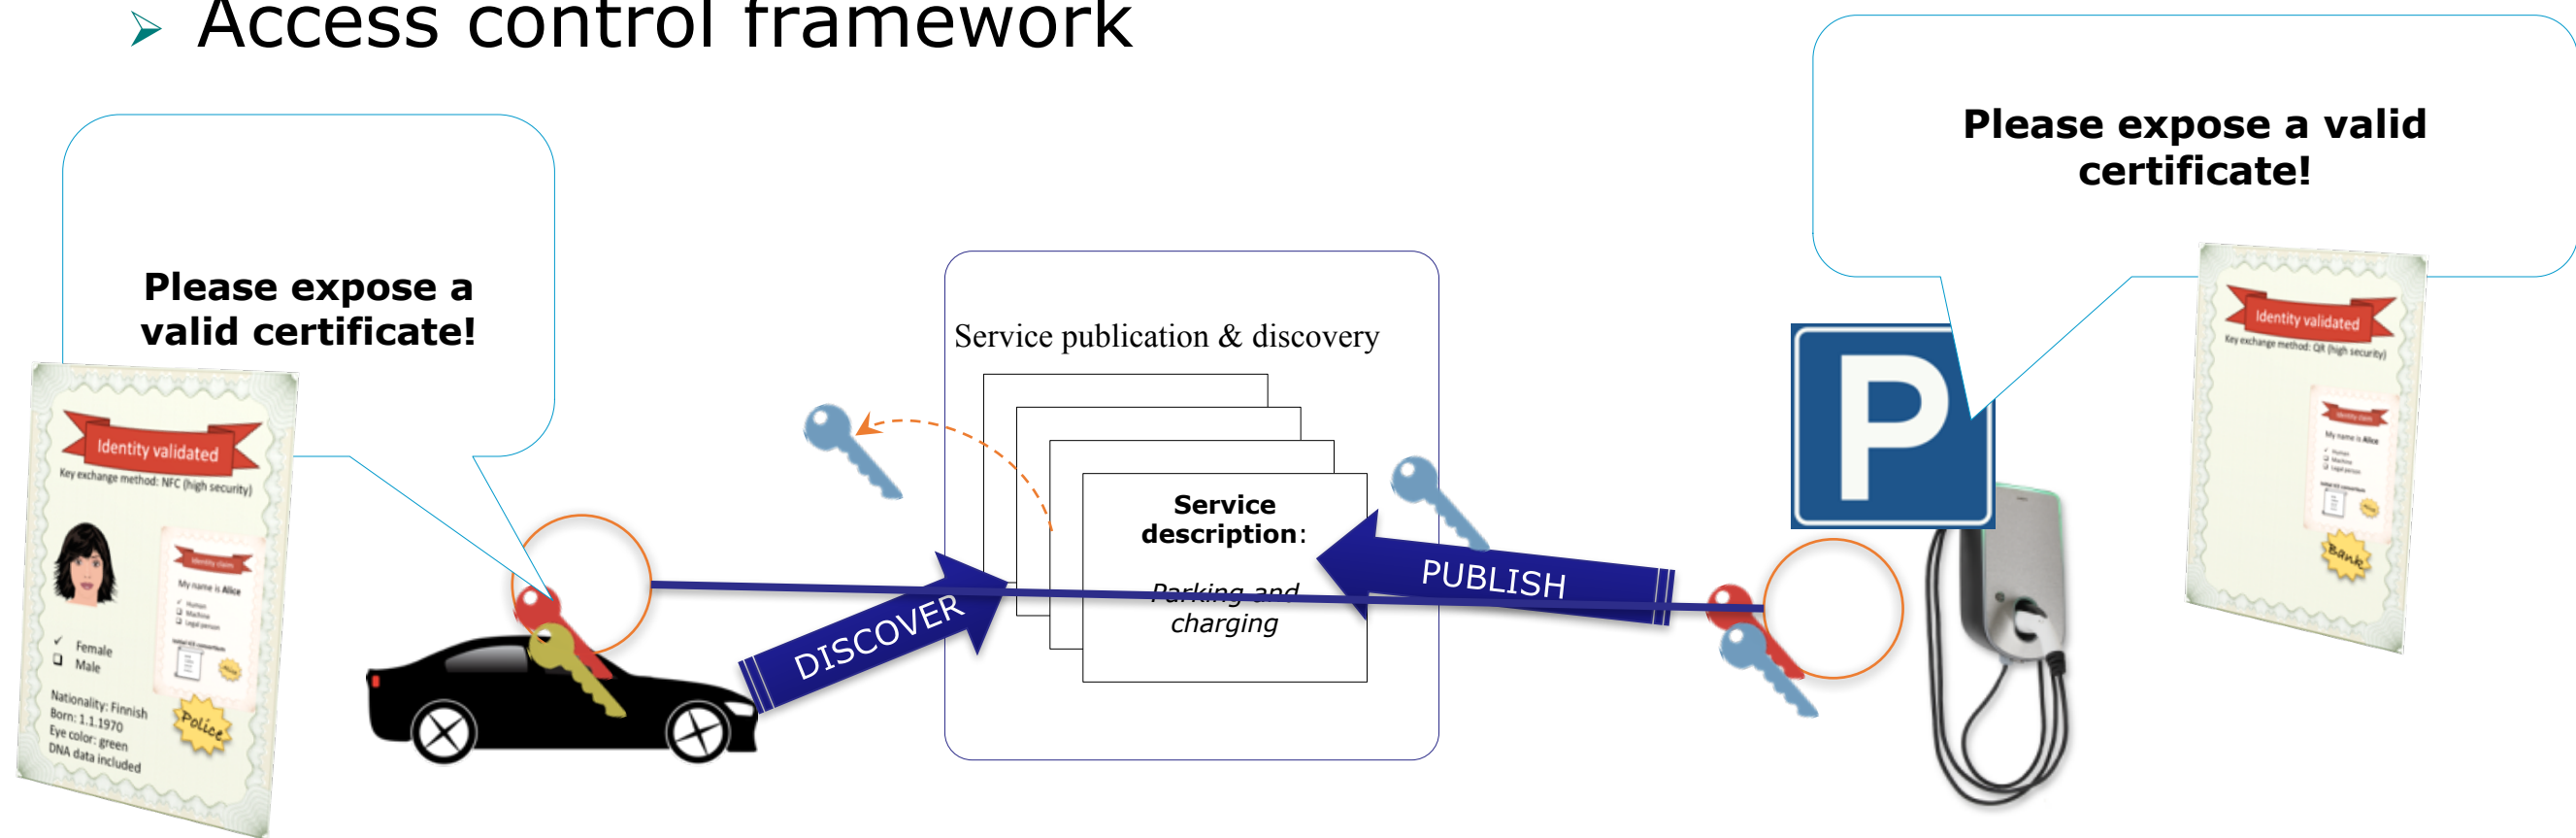

Hole in road 100
meters ahead!

Slippery 100 meters
ahead!

School class crossing
street in 5 minutes,
change route!

Trust framework

- Establish mutual trust, with ad hoc connections, no implicitly trusted third party
- Establish secure inter-service communication, peer-to-peer (authentication, encryption)
- Own identities for each service
- Access control framework

Create trust-relations (visually explained)

Length: 0:58

Trust-relations are roaming, even though both are moved to different NAT networks!

Commissioning

1. Power up a new Printer

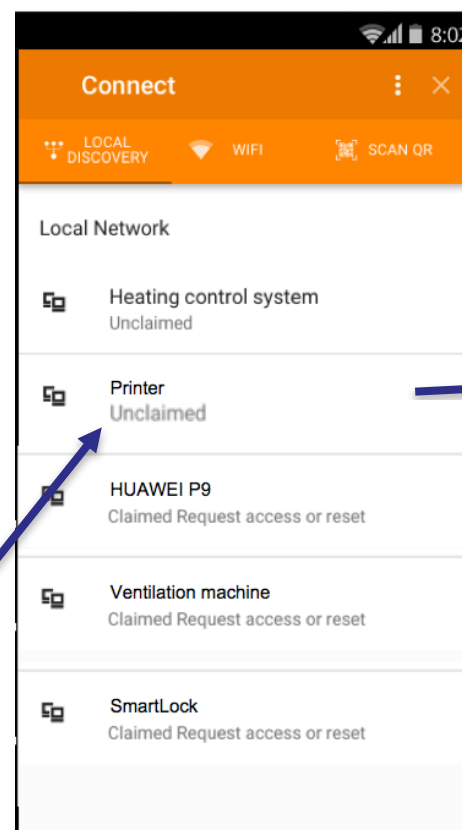

2. Add a new system in app

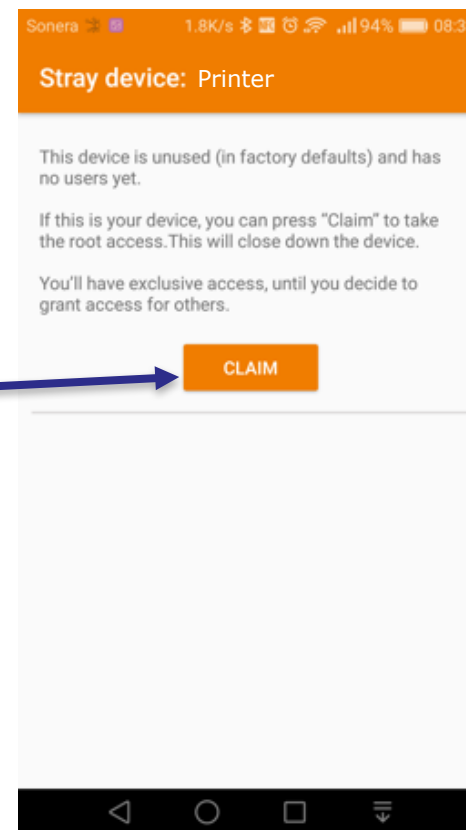

The Printer is ready to be accessed from an Android device on the same local subnet.

3. Use discovery

The trust-based stack will automatically detect available systems

4. Take the root account

The first user can take the root account (like when setting up a computer). This closes down the bus for future claiming attempts.

5. Access remotely and locally

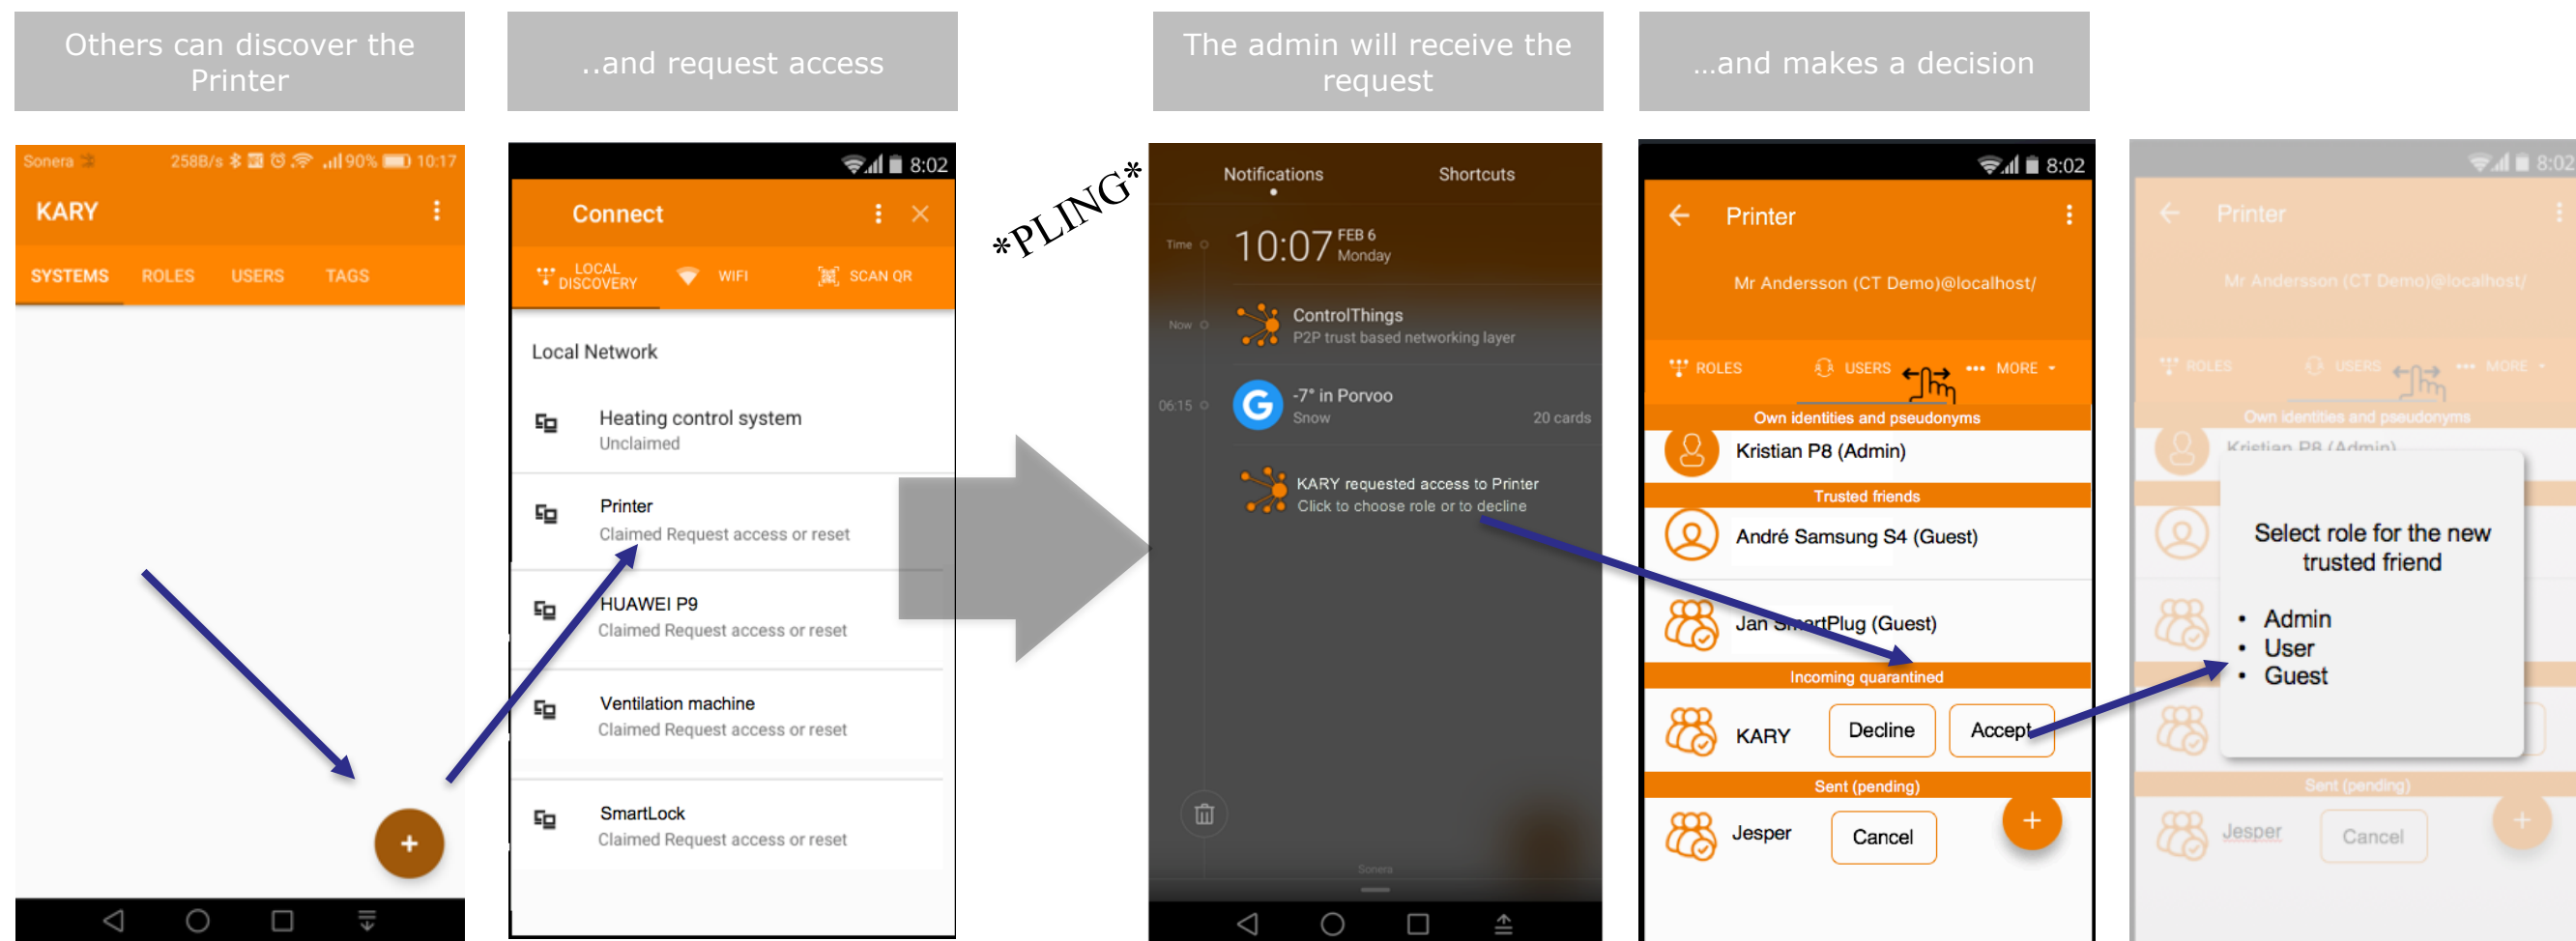

Access and control, even without cloud services. No need to configure any firewalls, NAT servers. No need for IP address or hostname hassle

MIST video

- Identity based communication.mp4
- From 4:45

Discovery, access request

Several parallel methods for creating trust-relations are supported, this is only an example. Invitations can be sent over social media, email, etc.

Conclusions

- IoT security basics are same as for any system
- However, IoT also gives many new challenges
- Most "IoT standards" tend to focus on communication in IoT and tend to neglect security aspects, such as Access Control
- The Open Group IoT standards O-MI and O-DF provide similar Access Control mechanisms as file system based Access Control
- Much remains to do for securing IoT systems on all levels

Thank You!
